Imaging for MIBC Trials: A Radiologist's Perspective

Jamie Marko, MD
Staff Clinician
Associate Research Physician
Department of Radiology and Imaging Sciences
NIH Clinical Center
Bethesda, MD

NIH Clinical Center
America's Research Hospital

Disclosures and Disclaimers

- No financial disclosures
- The content of this presentation is the responsibility of the presenter and does not necessarily represent the official views of the National Institutes of Health

NIH Clinical Center
America's Research Hospital

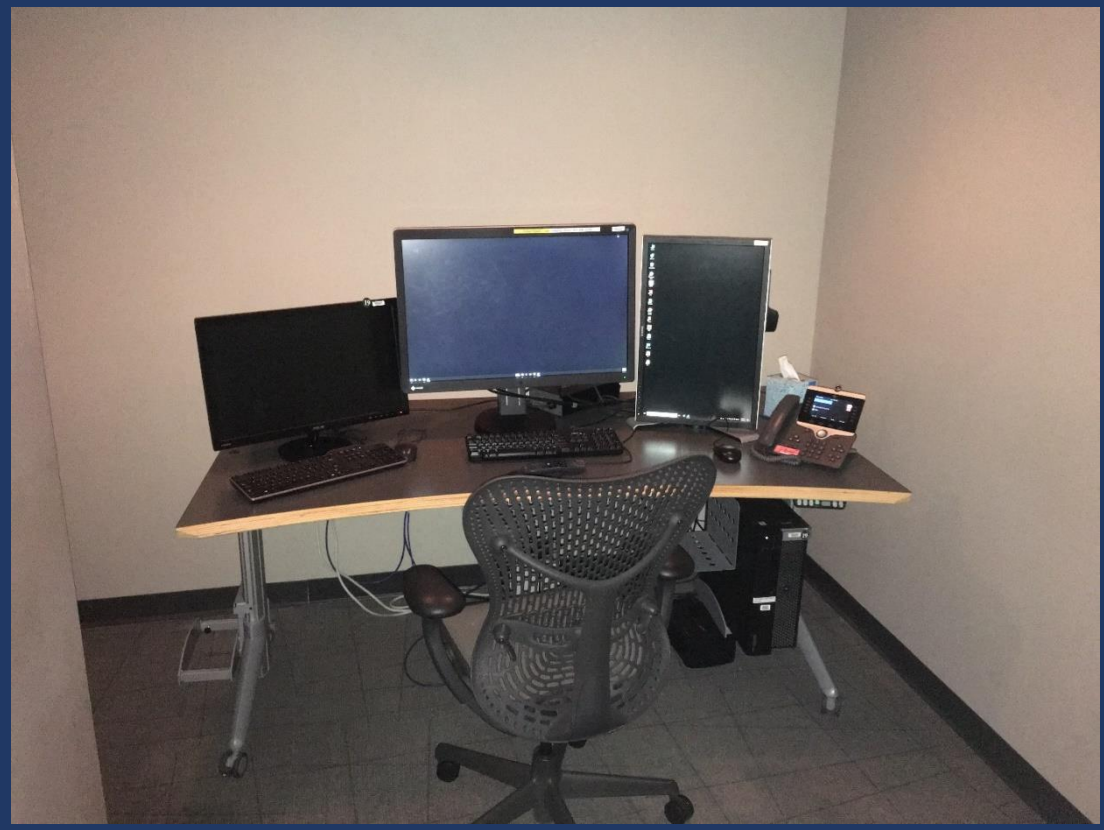
Objectives

- Review the recommendations from the panel for defining radiographic eligibility for adjuvant clinical trials in MIBC
- Review the recommendations from the panel for defining disease recurrence during an adjuvant clinical trial for MIBC
- Discuss potential future roles for imaging in the care of patients with MIBC

NIH Clinical Center
America's Research Hospital

Facts about Radiologists: The Good

- We are there to help
- Most of us are smart
- We have lots of training
- Our technology is constantly improving making our images amazing
- We are an independent voice objectively describing what we see
- We are trained in radiologic pathology



NIH Clinical Center
America's Research Hospital

Facts about Radiologists: The Bad

- Our technology is constantly changing, making much of our research outdated or obsolete
- We are not pathologists, so we describe what we see but often can't be sure
  - Clinical correlation anyone?

NIH Clinical Center
America's Research Hospital

We are not all the same!

- Radiologist A: very sensitive
  - Over callers
  - “I don’t want to miss anything so I will call that 7 mm LN a possible metastasis and recommend follow-up”
- Radiologist B: favors specificity over sensitivity
  - Under callers
  - “That 1.4 cm lymph node is probably just reactive, let’s give the patient a chance to declare themselves”

NIH Clinical Center
America's Research Hospital

- Radiologist C: follows standard teaching, uses best available data
  - “I use 1 cm short axis as my cut-off for LN metastases given its balance of sensitivity and specificity”

Helping Radiologist C

- Participating in interdisciplinary discussions, such as the FDA/NCI panel, gives Radiologist C a fighting chance by making standards available
- But as we move to a discussion of the standards that the panel suggests, please keep in mind that choice of standards affects the sensitivity and specificity of our imaging examinations

ROC curve

- Lymph node:
  - Short axis > 0.5 cm: high sensitivity, low specificity
  - Short axis > 1.5 cm: low sensitivity, high specificity
  - Short axis ≥ 1 cm: good balance of sensitivity and specificity
- Lack of data on exact sensitivity and specificity numbers for lymph nodes by cancer type and nodal stations

Objective 1: Defining Radiographic Eligibility

- Indication: MIBC. Evaluate prior to clinical trial enrollment
- Goal: Show that this patient has no evidence of disease (NED) prior to enrolling in an adjuvant trial

NIH Clinical Center
America's Research Hospital

General Radiology Practices

NIH Clinical Center
America's Research Hospital

What test to order?

NIH Clinical Center
America's Research Hospital

What test to order?

- CT of the chest, abdomen and pelvis with IV contrast within 4 weeks prior to trial enrollment
- Why?
  - Widely available
  - Technique can be standardized
  - Able to demonstrate the common manifestations of recurrent or metastatic MIBC

Eur J Radiol. 2017;97:119-130.
Urology. 1980;16(2):142-144.
Cancer Imaging. 2003;3(2):96-100.

How should the test be done?

NIH Clinical Center
America's Research Hospital

How should the test be done?

- Trials should adhere to imaging acquisition, display and radiologic interpretation technique as advised by the Quantitative Imaging Biomarker Alliance (QIBA)
- Why?
  - Affects rate of lesion detection
  - Affects size measurements

NIH Clinical Center
America's Research Hospital

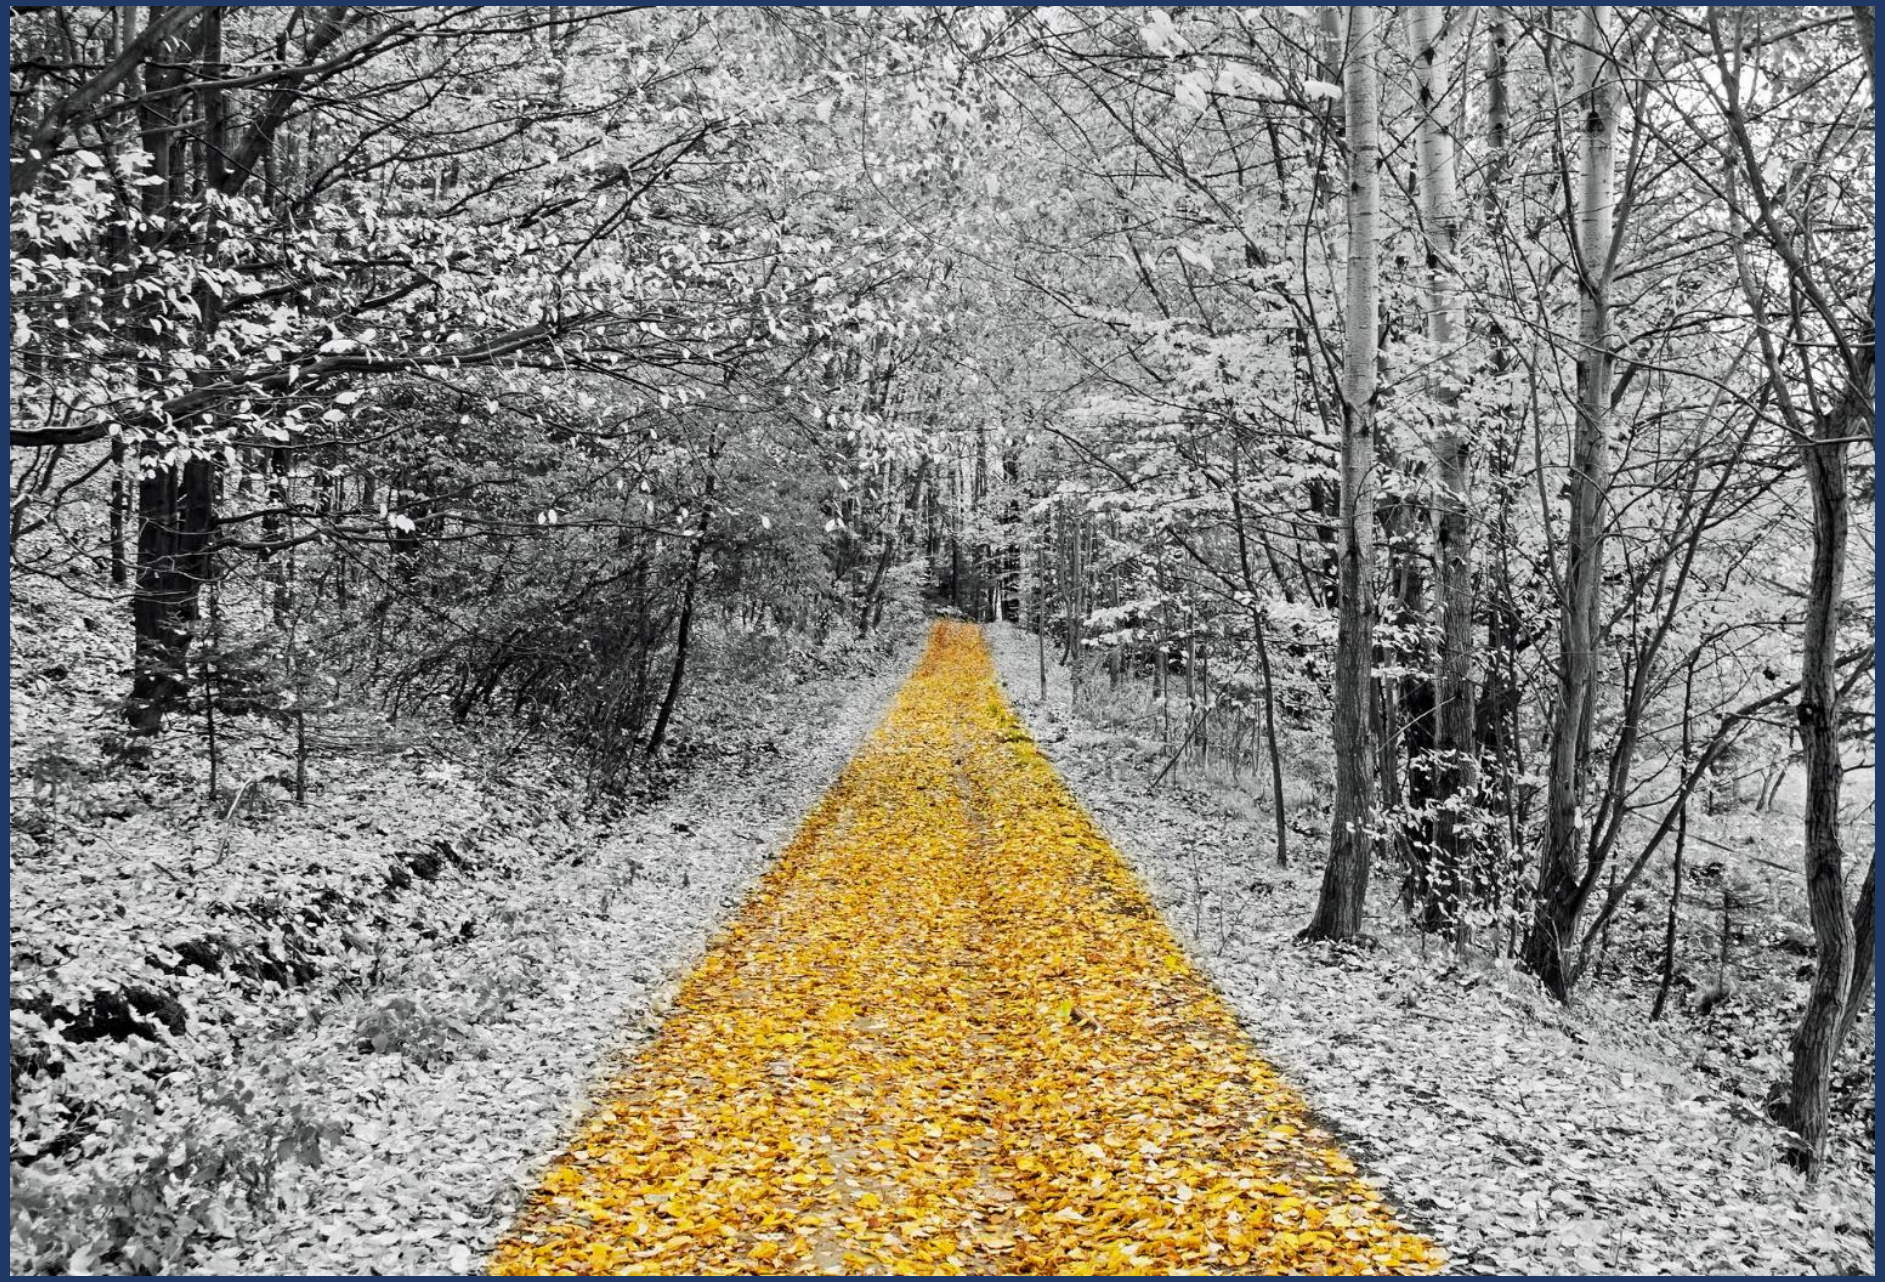
Radiology. 2003;226(1):231-234.
Radiology. 2005;234(3):934-939.

What about MRI and PET-CT?

- Although data show that MRI and PET-CT offer high specificity or negative predictive value, the differences are not substantial when compared directly to CT
- MRI and PET remain problem solving tools

NIH Clinical Center
America's Research Hospital

Curr Opin Urol. 2011;21(5):393-397.



Old Gold

- All prior relevant imaging examinations should be systematically archived
- Why?
  - Useful in clarifying equivocal findings at enrollment
    - 1.2 cm lung nodule
    - 2.1 cm hypodense liver lesion
    - 1.1 cm sclerotic bone lesion

NIH Clinical Center
America's Research Hospital

Interpretation Recommendations

NIH Clinical Center
America's Research Hospital

General Recommendation 1

- If there is an indeterminate lesion without prior studies available, the lesion should be considered benign if it is < 1 cm
  - 1 cm represent general consensus in radiology practice as to what is reasonably sensitive and specific for malignancy
  - 1 cm is the size needed to accurately characterize the density of a lesion at CT

NIH Clinical Center
America's Research Hospital

Eur J Radiol. 2017;97:119-130.
Radiology. 2010.;254(1):31-46.

General Recommendation 2

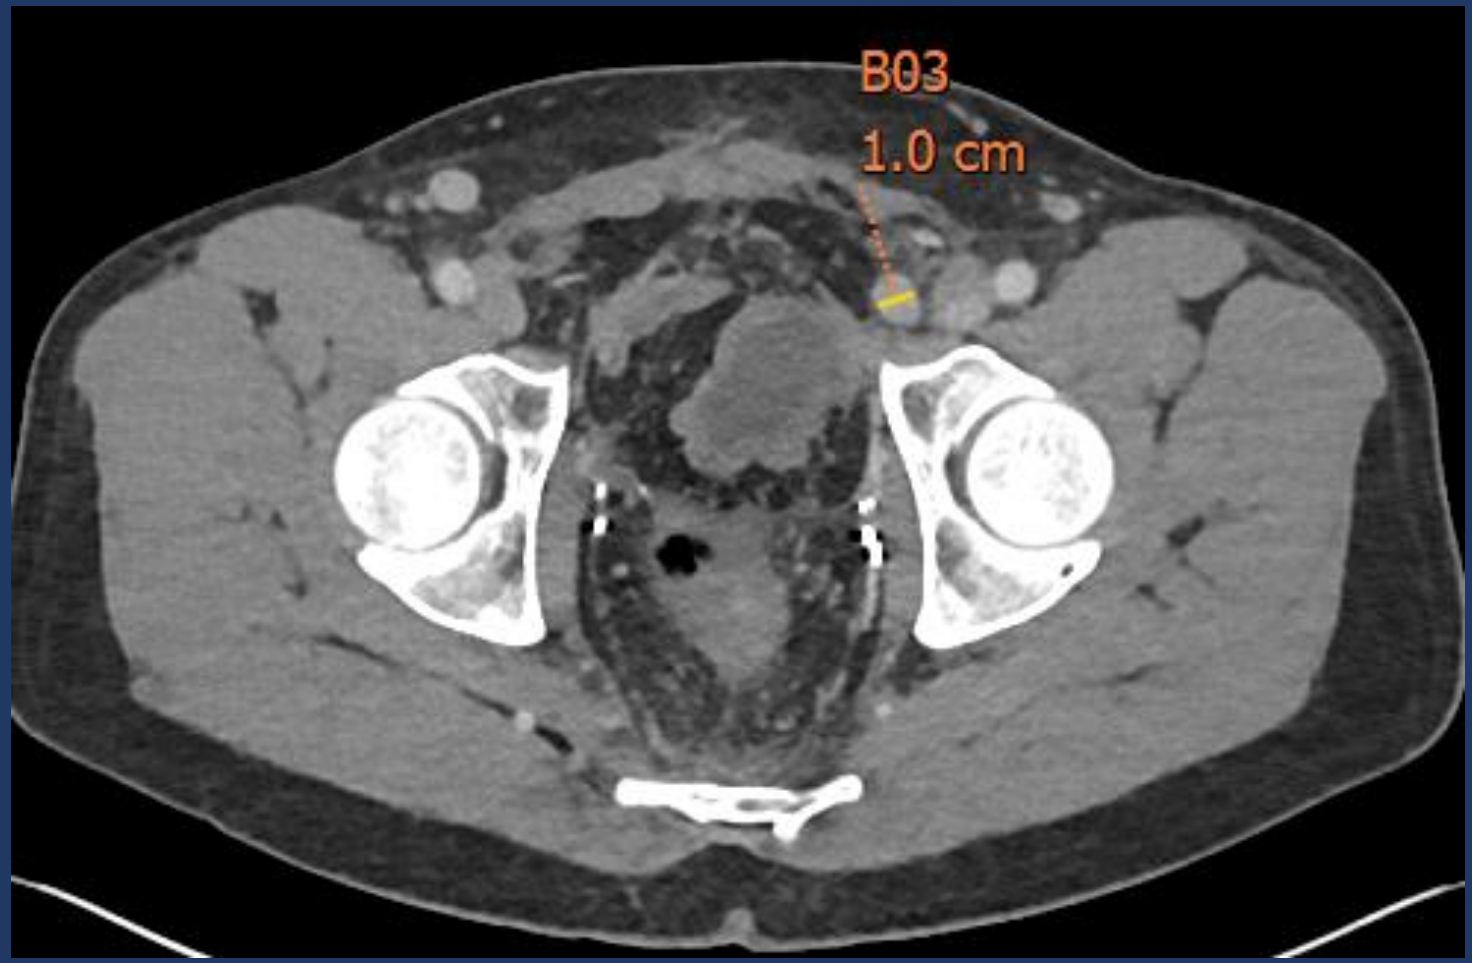
- An indeterminate lesion ≥ 1 cm should be regarded as suspicious for malignancy and should be further evaluated prior to trial enrollment
- Options for further evaluation include:
  - Customized radiologic work-up
  - Repeat CT imaging after an appropriate follow-up interval
  - Biopsy

NIH Clinical Center
America's Research Hospital

Site Specific Examples

NIH Clinical Center
America's Research Hospital

Case 1: Lymph node



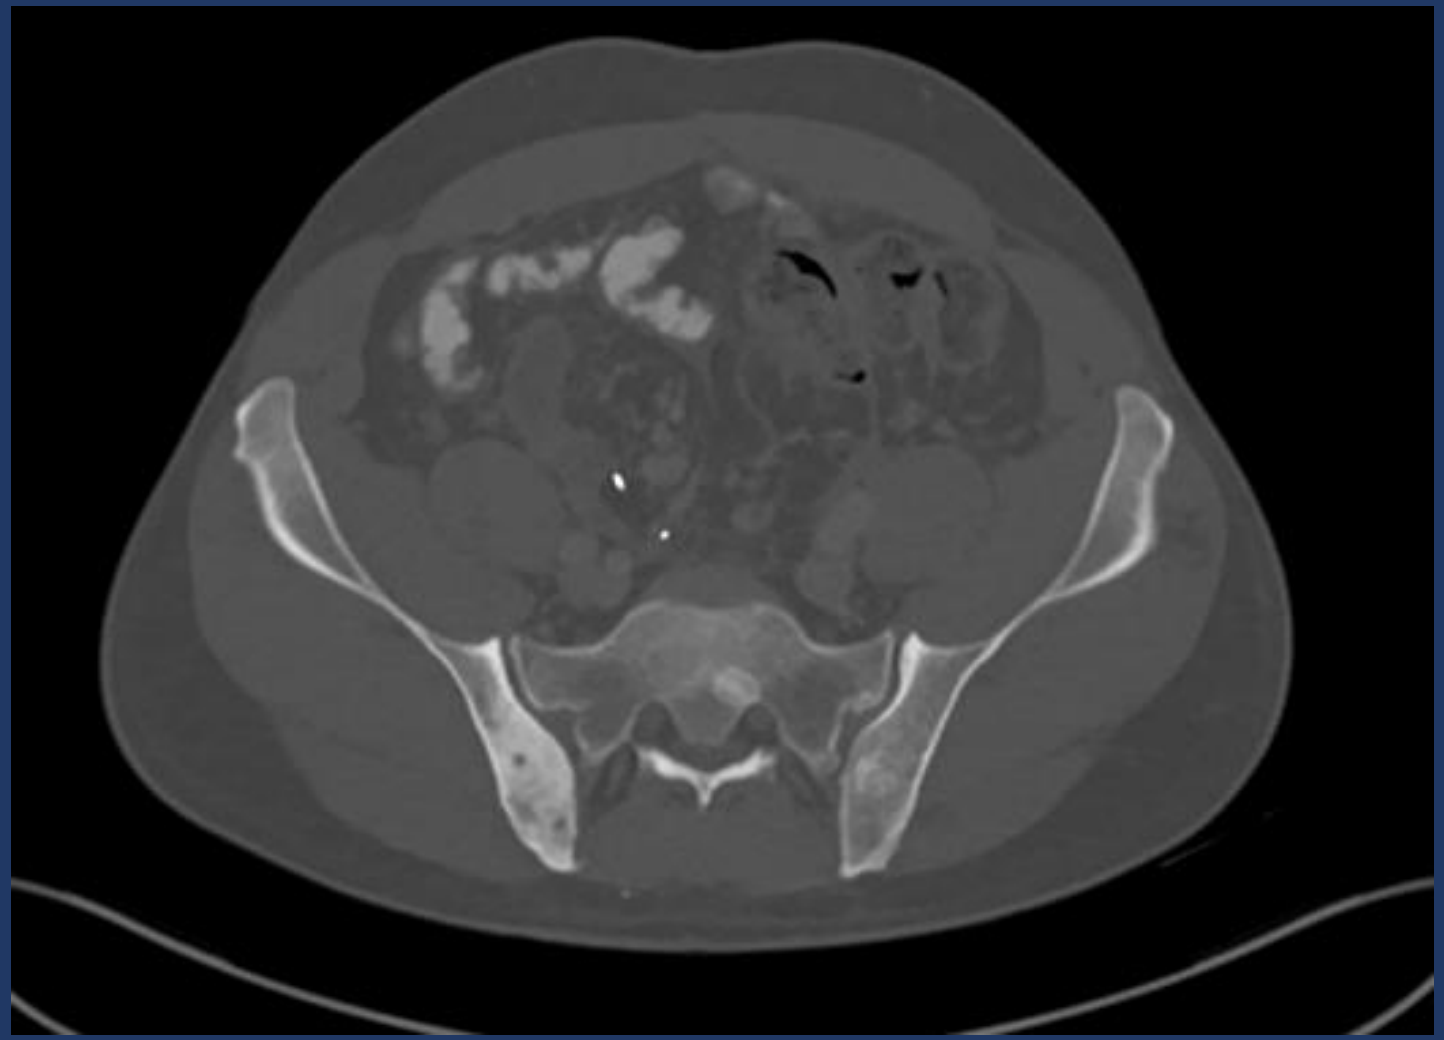
NIH Clinical Center
America's Research Hospital

Lymph Nodes Recommendation

- Customized radiologic work-up, follow-up imaging or biopsy:

≥ 1 cm in short axis

Case 2: Bone lesions



NIH Clinical Center
America's Research Hospital

Bone Lesion Recommendation

- Customized radiologic work-up, follow-up imaging or biopsy if:

≥ 1 cm in long axis

NIH Clinical Center
America's Research Hospital

Case 3: Liver Lesion

NIH Clinical Center
America's Research Hospital

Liver Lesion Recommendation

- Customized radiologic work-up, follow-up imaging or biopsy if:

≥ 1 cm in long axis

NIH Clinical Center
America's Research Hospital

Objective 2: Defining Disease Recurrence

- Indication: MIBC. Adjuvant trial surveillance
- Goal: Determine if there has or has not been disease progression while on trial using imaging

NIH Clinical Center
America's Research Hospital

Uniform Model for Defining Recurrence

NIH Clinical Center
America's Research Hospital

Uniform Model for Defining Recurrent MIBC

- New lesion ≥ 1 cm that was absent on initial imaging
  - Short axis for LN
  - Long axis for all other lesions

NIH Clinical Center
America's Research Hospital

Uniform Model for Defining Recurrent MIBC

- New lesion ≥ 1 cm that was absent on initial imaging
  - Short axis for LN
  - Long axis for all other lesions
- Pre-existing lesion:
  - If < 1 cm on previous exam, demonstrating > 50% growth on 2 consecutive exams with ≥ 5 mm absolute increase
  - If ≥ 1 cm on previous exam, demonstrating > 50% growth on a single exam

NIH Clinical Center
America's Research Hospital

Uniform Model for Defining Recurrent MIBC

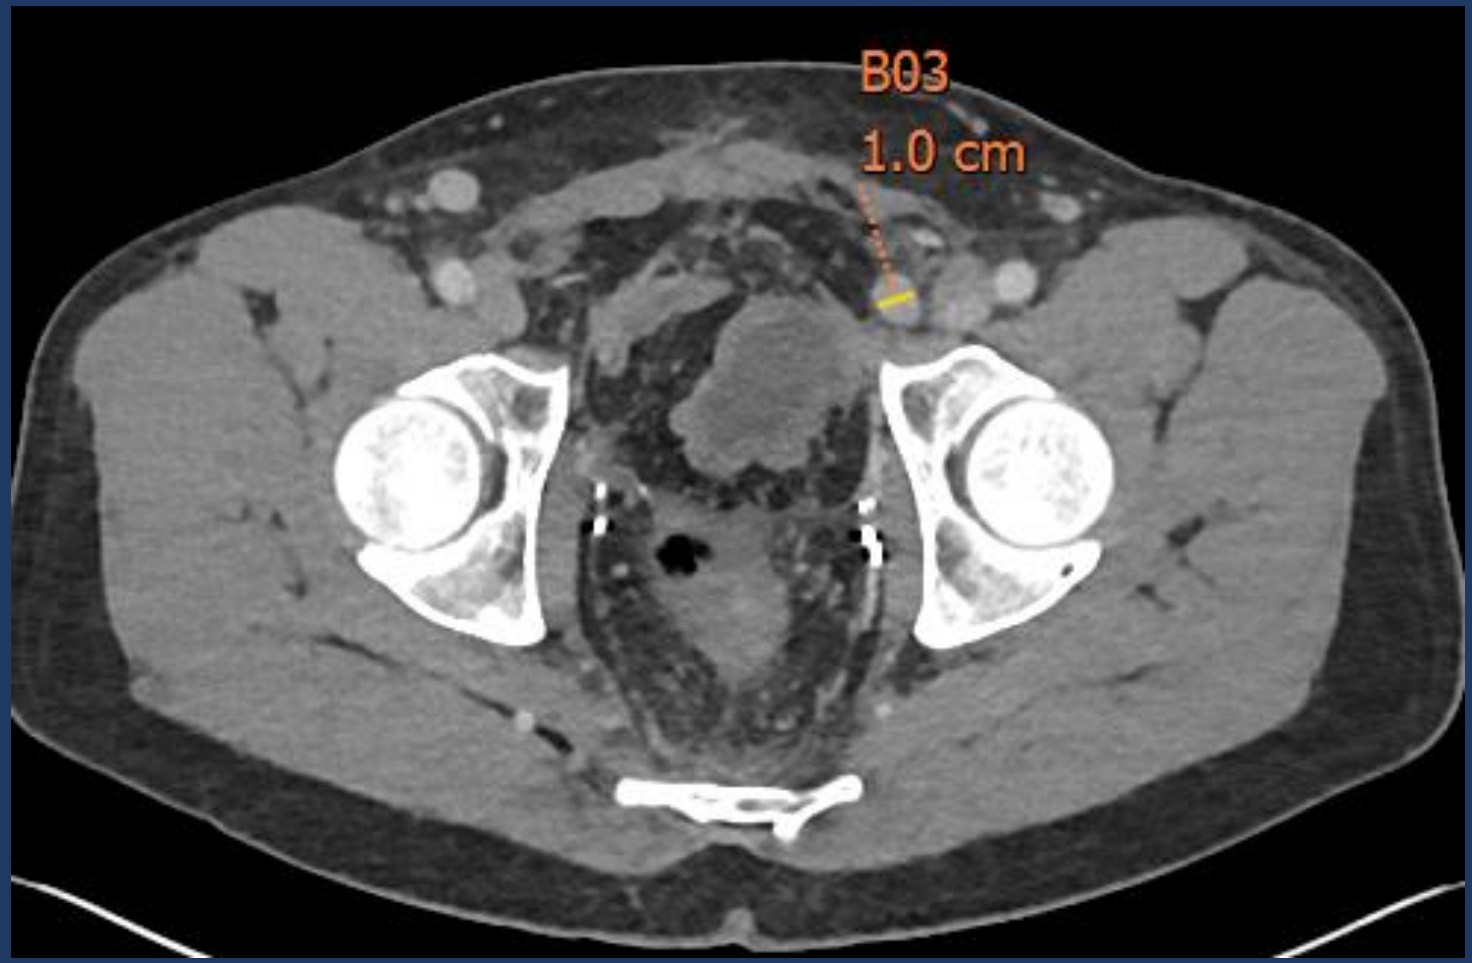
- New lesion ≥ 1 cm that was absent on initial imaging
  - Short axis for LN
  - Long axis for all other lesions
- Pre-existing lesion:
  - If < 1 cm on previous exam, demonstrating > 50% growth on 2 consecutive exams with ≥ 5 mm absolute increase
  - If ≥ 1 cm on previous exam, demonstrating > 50% growth on a single exam
- Multifocal lesions measuring <1 cm demonstrating geographic distribution or radiologic/metabolic features pathognomic for metastatic disease

NIH Clinical Center
America's Research Hospital

Site Specific Example

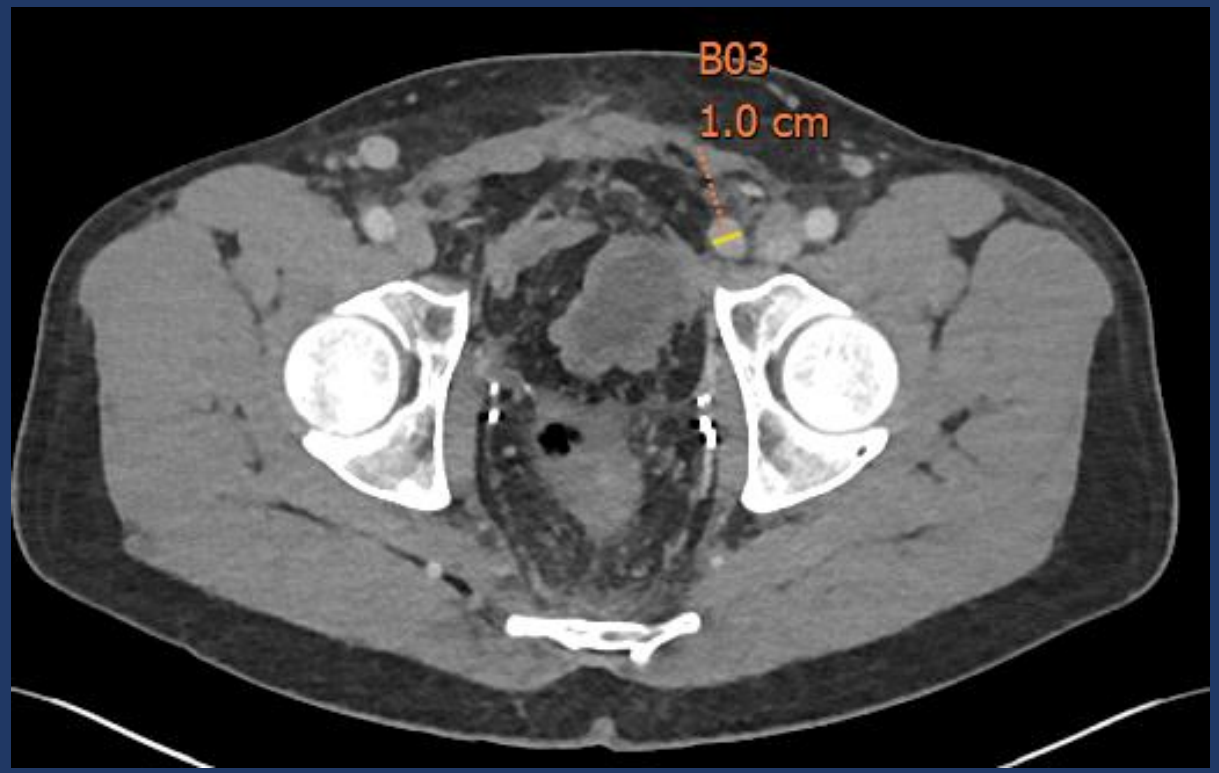
NIH Clinical Center
America's Research Hospital

Case 1: Lymph node



NIH Clinical Center
America's Research Hospital

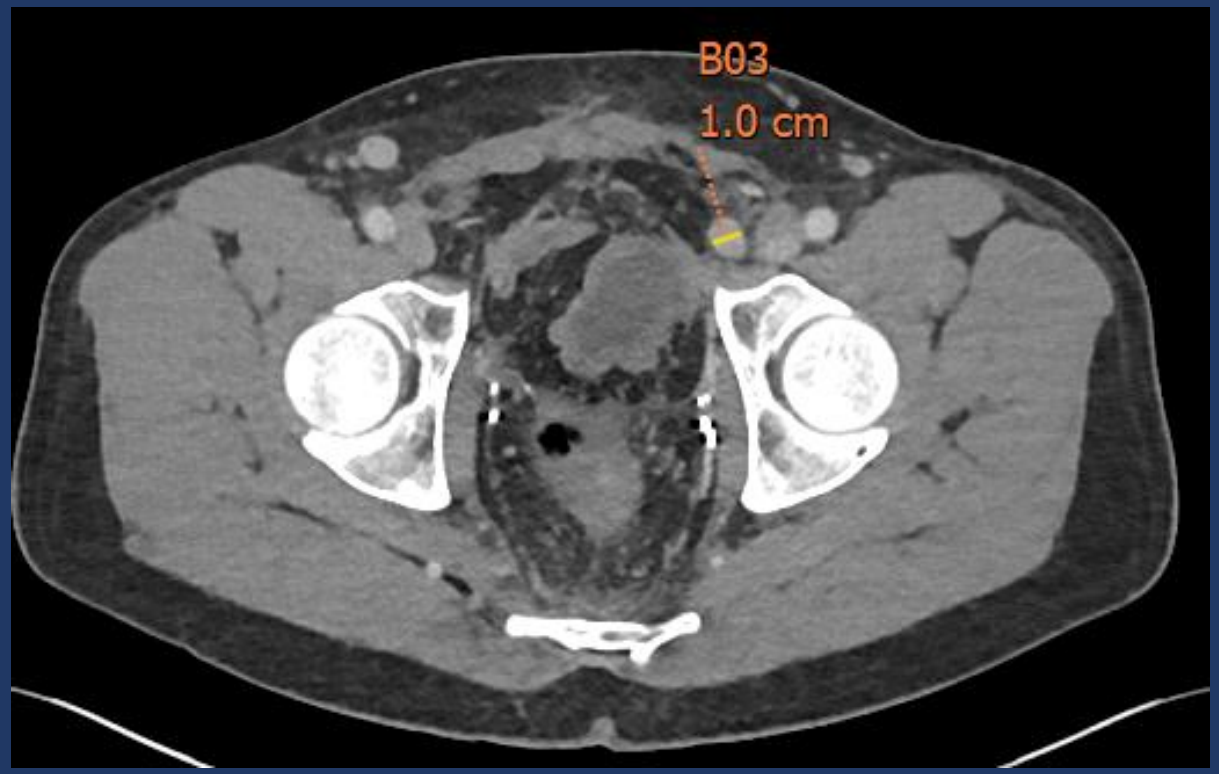
Case 1: Lymph node



- If new, then it is considered recurrent disease

NIH Clinical Center
America's Research Hospital

Case 1: Lymph node



- If pre-existing lesion, but negative for metastatic disease on customized radiologic work-up, follow-up CT or biopsy: would require >50% growth in short axis on 1 or 2 exams depending on the size on the eligibility CT

NIH Clinical Center
America's Research Hospital

Defining Date of Recurrence

- To backdate or not?
  - Backdating: using the date when a lesion was initially visible on imaging
    - More temporally accurate but introduces inconsistency
  - Not backdating: using the date when a lesion meets a pre-specified size criteria
    - More consistent but less temporally accurate

Defining Date of Recurrence

- We suggest that findings should not be backdated

NIH Clinical Center
America's Research Hospital

Future Radiologic Contributions

NIH Clinical Center
America's Research Hospital

The future

- Computer revolution
  - Radiogenomics
  - Artificial intelligence
  - Big data and deep learning
- Optimization of current techniques
  - DWI
  - DCE imaging
  - Lymphotropic nanoparticle enhanced MRI (superparamagnetic iron oxide)
- Novel imaging agents
  - ^{64}Cu-TP3805 PET-CT (VPAC receptors)

Thank you
